With NO mem mgrs installed at all, Setup for Build 61d & RC1 Abend with "Standard Mode: Fault in MS-DOS Extender" & a register dump. So, couldn't even get that far. Ideas? Thanks a lot,  
-greg

Greg -

I've been running under DR6 for the last three builds without any problems except the error message upon startup. I did have to boot an older version of msdos to run the DOS portion of setup, since it would crash switching into protected mode, but that may have been a QEMM 6 problem, 'cause I've been crashing MSD with QEMM (but not 386^MAX). I even used Superpck and SuperStor from DR6 and QEMM with my msdos boot disk (instead of smartdrive & himem & emm386) and it went just fine.

They (msdos 5 & drdos 6) are both great programs -- I just prefer drdos for their enhancements to config.sys that let me switch among (at last count about 15) different setups by selecting from a menu.

- Gary.

I experienced the same crash on switch to protected mode. Will try your suggestions. Many thanks,  
-greg
